Case 104

The prechemotherapy image (left) shows intense hypermetabolism in the abdominal, pelvic and left inguinal nodes, consistent with known diagnosis of lymphoma. There is probable involvement of the left submandibular node also. The post therapy image (right) shows resolution of the hypermetabolic foci and no definite evidence of active neoplastic disease, suggesting good and complete response to therapy. Moderate diffuse bone marrow activity is secondary to chemotherapy. Linear, intense activity in the descending colon could be physiologic or from colitis.
